## Description

## Background of the Invention

Mammals, both humans and animals, are known to suffer from various conditions involving inflammation of the bowels. Such conditions are typically characterized by unpleasant symptoms such as diarrhea, cramping and loss of appetite. Certain of the conditions, in particular ulcerative colitis, are also characterized by patches of ulceration. Accordingly, there is a need for a safe drug which will decrease the severity of bowel inflammation and alleviate the symptoms associated therewith.

Teuber *et al.*, *Liebigs Ann. Chem.*, 757 (1978) discloses 5-([3,5-bis(1,1-dimethylethyl)-4-hydroxyphenyl]-methylene)-2-thioxo-4-thiazolidinone as an intermediate in the preparation of certain compounds, which are in turn used for the spin-labeling of peptides. No biological activity is disclosed for this intermediate compound.

European Patent Application 211,670 discloses certain di-*t*-butylphenol substituted rhodanine derivatives which are useful in treating inflammation, stroke and arthritis in mammals. The inflammatory conditions which may be treated using the reference compounds involve inflammation of skin tissue and joint swelling. Such conditions are commonly associated with diseases such as rheumatoid arthritis, rheumatoid spondylitis, osteoarthritis, degenerative joint diseases and the like. Methods for treating inflammatory conditions involving inflammation of the bowels are not disclosed.

The present invention provides the use for preparing a medicament for of treating inflammatory bowel disease in a mammal suffering from said disease, or susceptible to said disease, of a compound of the Formula (I)

Some of the compounds employed in the use of the present invention are known, see, e.g., European Patent Application 211,670 and Teuber *et al.*, *Leibigs Ann. Chem.*, 757 (1978). However, the majority of the compounds used in the method of the present invention, as well as the compounds of the present invention, are novel. In general, these compounds may be synthesized as follows.

Teuber *et al.* disclose 5-[[3,5-bis(1,1-dimethylethyl)-4-hydroxyphenyl]methylene]-2-thioxo-4-thiazolidinone (referred to in the following discussion as Compound A). The compound is prepared by reacting 3,5-di-tert-butyl-4-hydroxybenzaldehyde with rhodanine at reflux temperature in glacial acetic acid using fused sodium acetate as catalyst. 5-[[3,5-bis(1,1-dimethylethyl)-4-hydroxyphenyl]methylene]-4-thiazolidinone (Compound B), 5-[[3,5-bis(1,1-dimethylethyl)-4-hydroxyphenyl]methyl]-4-thiazolidinone (Compound C) and 5-[[3,5-bis(1,1-dimethylethyl)-4-hydroxyphenyl]methyl]-2-thioxo-4-thiazolidinone (Compound D) can be prepared from Compound A.

For example, when Compound A is subjected to catalytic hydrogenation, one obtains both Compounds B and C. The relative proportions obtained depend upon the temperature, pressure, and duration of hydrogenation, the solvent employed, and the particular catalyst used. For example, when Compound A is treated with 5% palladium on carbon in ethanol at 100°C for approximately 18 hours, the relative ratios of Compound B: C are approximately 60:40. Alternatively, these transformations may be accomplished by heating Compound A in a mixture of hydrochloric acid and an alcohol, such as ethanol, in the presence of zinc. Reduction of the thione without affecting the benzylic double bond may be accomplished by heating the thione with a reducing agent such as tri-n-butyl tin hydride in a non-reactive solvent, such as toluene, and preferably in the presence of a free radical initiator, such as azobisisobutyronitrile. However, for such reduction to work an N-substituted rhodanine substrate (i.e., Q cannot be -NH) must be employed.

The transformation of Compound A to D may be accomplished by a variety of methods known in the art. A preferred method is that taught by Nakamura *et al.*, *Tetrahedron Letters*, 25, 3983 (1984). In this reaction, Compound A is treated with a dihydropyridine such as diethyl 2,6-dimethyl-1,4-dihydro-3,5-pyridinedicarboxylate in the presence of silica gel. The reaction is best carried out in the presence of a nonreactive solvent such as benzene or toluene, preferably under an inert atmosphere. The reaction may be accomplished at temperatures from about 25°C up to the reflux temperature of the mixture. At the preferred temperature of approximately 80°C, the reaction is essentially complete after 12-18 hours.

Other thiazolidinones may, depending on the values selected for the various substituents, be prepared in an analogous fashion. For example, compounds of Formula I and Formula II wherein Q is NR<sup>8</sup> and R<sup>8</sup> is hydrogen, C<sub>1</sub>-C<sub>6</sub> alkyl, C<sub>3</sub>-C<sub>8</sub> cycloalkyl or -(CH<sub>2</sub>)<sub>n</sub>-Y, where n is an integer from 0 to 3, both inclusive, and Y is cyano or NR<sup>11</sup>R<sup>12</sup> where R<sup>11</sup> and R<sup>12</sup> are each independently hydrogen or C<sub>1</sub>-C<sub>6</sub> alkyl, may be prepared by the method of Teuber *et al.* described above, employing the appropriate N-substituted rhodanine and R<sup>1</sup>, R<sup>2</sup>-substituted-4-hydroxybenzaldehyde. Alternatively, rhodanine may be used for the condensation with the aldehyde to form those species wherein Q is NR<sup>8</sup> and R<sup>8</sup> is hydrogen, followed by alkylation with the appropriate R<sup>8</sup>-containing halide, such as an iodide or bromide, to provide the corresponding N-substituted derivatives, i.e., those compounds of Formulae I or II in which R<sup>8</sup> is C<sub>1</sub>-C<sub>6</sub> alkyl, C<sub>2</sub>-C<sub>6</sub> alkenyl, C<sub>3</sub>-C<sub>8</sub> cycloalkyl, or -(CH<sub>2</sub>)<sub>n</sub>-Y, where Y is cyano, OR<sup>9</sup>, -SH, -S(C<sub>1</sub>-C<sub>4</sub> alkyl), -NR<sup>11</sup>R<sup>12</sup> or

and n, R<sup>9</sup>, R<sup>11</sup> and R<sup>12</sup> are as defined for Formula I. The alkylation is usually accomplished in an inert solvent such as tetrahydrofuran (THF) or dimethylformamide (DMF) in the presence of a strong base such as sodium hydride. In a similar fashion, rhodanine may be used for the condensation with the aldehyde to form those species wherein Q is NR<sup>8</sup> and R<sup>8</sup> is hydrogen followed by acylation with the appropriate R<sup>8</sup>-containing halide to provide N-substituted derivatives of Formulae I or II in which R<sup>8</sup> is -(CH<sub>2</sub>)<sub>n</sub>-Y and Y is

where  $n$  and  $R^{10}$  are as defined for Formula I.

Compounds of Formulae I and II wherein  $Q$  is  $\text{NR}^8$  and  $R^8$  is  $-(\text{CH}_2)_n\text{-Y}$  ( $Y$  is  $\text{OR}^9$  or  $\text{NR}^{11}\text{R}^{12}$ , wherein  $R^9$  is hydrogen, acetyl or tosyl and  $R^{11}$  and  $R^{12}$  are as defined for Formula I) may also be prepared according to the following reaction scheme:

A hydroxyalkyl rhodanine III is prepared by condensing carbon disulfide, chloroacetic acid, and the appropriate hydroxyalkylamine by standard techniques. When condensed with the appropriate  $\text{R}^1, \text{R}^2$ -substituted-4-hydroxybenzaldehyde, as described above, the resulting product is the condensed 2-thioxo-4-thiazolidinone IV, which has been transformed into the acetyl derivative. The thioxo compound may optionally be converted to the methylene compound of formula V as described above. The acetyl group of intermediate V may be removed upon treatment with aqueous ammonia in a solvent such as acetonitrile to provide compound VI (i.e., the compound of Formulae I and II wherein  $Q$  is  $\text{NR}^8$  and  $R^8$  is  $-(\text{CH}_2)_n\text{-Y}$  where  $Y$  is  $\text{OR}^9$  and  $R^9$  is hydrogen). The hydroxy compound VI is then converted to the tosyl derivative (VII) upon treatment with *p*-toluenesulfonyl chloride in pyridine, preferably at a temperature of around

0°C. The versatile tosyl intermediate VII may then be transformed into additional compounds of Formulae I and II upon treatment with an appropriate  $\text{HNR}^{11}\text{R}^{12}$  amine, where  $\text{R}^{11}$  and  $\text{R}^{12}$  are as stated in the preceding paragraph. This latter transformation is best accomplished by allowing VII to react in the presence of a molar excess of the amine. Once again, a solvent such as acetonitrile is useful for accomplishing this transformation.

The corresponding 1,3-oxothiolan-5-ones of Formulae I and II may be prepared from  $\beta$ -(3,5-di-*t*-butyl-4-hydroxyphenyl)- $\alpha$ -mercaptoacrylic acid (IX). Compound IX may be treated with carbon disulfide to prepare the thione analog (Formulae I and II, Q is -O-,  $\text{R}^6$  and  $\text{R}^7$  are =S), while reaction of IX with formic acid provides the corresponding desthione (Formulae I and II, Q is -O-,  $\text{R}^6$  and  $\text{R}^7$  are each hydrogen). Compound IX can be prepared by known methods (see, e.g., Campaigne *et al.*, *J. Org. Chem.*, **26**, 359 (1961); *id.*, **26**, 1326 (1961); Chakrabarti, *et al.*, *Tetrahedron*, **25**(14), 2781 (1969)), or upon heating Compound A with dilute aqueous base.

Compounds of Formulae I and II wherein Q is  $\text{NR}^8$  and  $\text{R}^8$  is  $-(\text{CH}_2)_n\text{-Y}$  ( $n=0$ ) and Y is  $\text{NR}^{11}\text{R}^{12}$ , where  $\text{R}^{11}$  and  $\text{R}^{12}$  are as defined for Formula I, may be prepared according to the following reaction sequence:

The  $\text{R}^{11}$ -substituted hydrazine is treated with benzaldehyde in an alcoholic (preferably methanol) solvent to yield intermediate X, which, in turn, is reacted with the appropriate  $\text{R}^{12}$ -halide in the presence of triethylamine and acetonitrile to render intermediate XI. XI is then treated with hydrazine to render the  $\text{R}^{11}, \text{R}^{12}$ -hydrazine, XII. XII may alternatively be prepared by reducing a nitroso- $\text{R}^{11}\text{R}^{12}$  amine using zinc dust and acetic acid or aluminum and a strong

base. The nitroso- $R^{11}R^{12}$  amine itself is prepared from an  $R^{11}, R^{12}$  amine as described in *J. Am. Chem. Soc.*, **77**, 790 (1955) by treatment with sodium nitrite in HCl. XII is then treated with carbon disulfide, chloroacetic acid and triethylamine to yield intermediate XIII. Condensation of XIII with the appropriate  $R^1, R^2$ -substituted-4-hydroxybenzaldehyde (i.e.,  $ArCHO$ ) renders XIV. As described previously, the thione may be reduced by treatment with a reducing agent such as tri-n-butyl tin hydride in a non-reactive solvent such as toluene, preferably in the presence of a free radical initiator such as azobisisobutyronitrile. Preparation of the species wherein one of  $R^{11}$  or  $R^{12}$  is hydrogen may be effected before or after reduction of the thione, as desired, by heating the disubstituted compound in a mixture of ethanol/water in the presence of a catalyst, such as a rhodium catalyst.

Those compounds of Formulae I and II wherein X is

and m is 1 or 2 are readily prepared from the sulfide (i.e.,  $m=0$ ) by treatment with an oxidizing agent, such as m-chloroperbenzoic acid, in an appropriate organic solvent, such as chloroform, for a time sufficient to effect the desired oxidation.

Compounds of Formulae I and II wherein  $R^3$  is  $C_1-C_6$  alkyl are prepared by conventional Friedel-Crafts alkylation of the appropriate  $R^1, R^2$ -substituted phenol, followed by condensation with rhodanine, or the desired N-substituted rhodanine, as described herein, or is used as described in other reaction schemes depicted herein.

It will be readily appreciated by one skilled in the art that the aryl portion of the present compounds of Formulae I and II are either commercially available or may be readily prepared by known techniques from commercially available starting materials. For example, p-hydroxybenzaldehyde may be alkylated under Friedel-Crafts conditions to yield an alkylbenzaldehyde which in turn may itself be alkylated. Similarly, the rhodanine or N-substituted rhodanine starting material is either commercially available or may be prepared by well known methodology from commercially available starting materials.

Those compounds of Formulae I and II wherein one of  $R^6$  or  $R^7$  is hydrogen and the other is  $-OH$  (and X is

where m is 0) are conveniently prepared from their precursors of Formulae I and II where  $R^6$  and  $R^7$  are both hydrogen (and X is

where m is 1) by treatment of the precursor with, for example, trifluoroacetic anhydride in an inert solvent (preferably methylene chloride) at reduced temperatures. Similarly, compounds of Formulae I and II where, in the definition of Q, Y is cyano are prepared by treating the non-cyanated analog with the desired halo-substituted aliphatic nitrile. From the cyano derivative, the tetrazolyl is prepared by treatment with tri-n-butyl tin azide in, for example, ethylene glycol dimethyl ether. Other compounds of Formulae I and II may be prepared as more fully described below from compounds whose synthesis was described generically, *supra*.

The use and compounds of the present invention encompass both the racemate and its individual stereoisomers. In general, the stereoisomers may be obtained according to procedures well known in the art. However, for compounds of Formulae I and II wherein X is  $-S-$ ;  $R^4$  and  $R^5$  are hydrogen; and  $R^1, R^2, R^3, R^6, R^7$  and Q are as defined for those Formulae, the individual stereoisomers may be isolated in substantially pure isomeric form according to the following novel process. In the following process, preferred compounds whose stereoisomers may be isolated are those compounds of Formulae I and II wherein X is  $-S-$ ;  $R^4$  and  $R^5$  are hydrogen; and  $R^1, R^2, R^3, R^6, R^7$  and Q are as defined for the preferred, somewhat preferred, particularly preferred, especially preferred and most preferred compounds of the use of the present invention.

The racemic sulfide compound of Formulae I or II is reacted with a reagent prepared by combining a tartrate ligand,

a titanium alkoxide, a hydroperoxide and, optionally, water. Suitable titanium alkoxides for use in the present process include titanium alkoxides having the formula  $\text{Ti}(\text{C}_1\text{-C}_4 \text{ alkoxy})_4$ . A particularly preferred titanium alkoxide is one wherein the  $\text{C}_1\text{-C}_4$  alkoxy group is isopropoxy. Similarly, suitable tartrate ligands for use in the present process include the di( $\text{C}_1\text{-C}_4$  alkyl) tartrates, with diethyl tartrate or diisopropyl tartrate particularly preferred. Finally, suitable hydroperoxides which may be used in the present process include cumenehydroperoxide, *t*-butylhydroperoxide, and the like. A particularly preferred hydroperoxide is *t*-butylhydroperoxide.

The present reaction is conducted by mixing the above reagents in an inert solvent. Suitable inert solvents include aromatic solvents such as toluene and the like; halogenated alkanes such as methylene chloride, 1,2-dichloroethane, chloroform and the like; ethers such as tetrahydrofuran, diethyl ether and the like; and ketones such as acetone and the like. A particularly preferred inert solvent is methylene chloride. In general, the amount of solvent used should be sufficient to ensure that all compounds stay in solution during reaction. However, excessive amounts of solvent should be avoided since unnecessary product loss may occur during product isolation.

The amount of titanium alkoxide used in the present reaction is not critical. The titanium alkoxide may be employed in quantities of from about 0.4 equivalents to about 2.0 equivalents relative to the racemic sulfide starting material. For reasons explained more fully below, the titanium alkoxide is preferably employed in quantities sufficient to provide a titanium alkoxide/sulfide substrate ratio of from about 0.5/1.0 to about 0.75/1.0. If the titanium alkoxide is used in less than equimolar quantities relative to the sulfide starting material, 3Å- or 4Å- molecular sieves may be added, if desired, to avoid the possibility of water deactivation of the titanium complex.

The amount of tartrate ligand, hydroperoxide and water employed are based on the amount of titanium alkoxide used, and are also not critical. In general, the tartrate ligand is employed in quantities sufficient to provide a tartrate ligand/titanium alkoxide ratio of from about 1/1 to about 5/1, with a preferred ratio being about 2/1. Similarly, the hydroperoxide may be employed in from about equimolar quantities relative to the titanium alkoxide to about two equivalents relative to that same compound. The amount of water employed may vary from anhydrous reaction condition (i.e. no equivalents of water) to as much as about 5 equivalents of water relative to the amount of titanium alkoxide present. When anhydrous reaction conditions are employed, the tartrate ligand should be used in an amount sufficient to provide a tartrate ligand/titanium alkoxide ratio corresponding to the higher end of the tartrate ligand/titanium alkoxide ratio described above.

The stereochemistry of the tartrate ligand determines which stereoisomer will be obtained from the racemic sulfide substrate. For example, if (+)-diisopropyltartrate is employed in the present reaction the (-) enantiomer of the sulfide starting material will be isolated in substantially pure isomeric form. Correspondingly, if (-)-diethyltartrate is used, substantially pure (+) enantiomer of the sulfide substrate will be obtained. Accordingly, the tartrate ligand must be chosen so that its stereochemistry is opposite that of the isomeric form desired.

The racemic sulfide substrate of the present process is reacted with the reagent prepared from the titanium alkoxide, the tartrate ligand, the hydroperoxide and, optionally, water until substantially all of the undesired enantiomer of the sulfide starting material has been converted to its sulfoxide analog. Conversion to the sulfoxide readily occurs at temperatures in the range of from about -50°C to about 50°C, with a preferred temperature being about -20°C. Once substantially all of the undesired enantiomer has been converted to its sulfoxide analog, the reaction is terminated by quenching the reaction mixture according to techniques well known in the art.

To ensure that substantially all of the undesired enantiomer is converted to the sulfoxide, while minimizing conversion of the desired enantiomer, only about 50 to about 70 percent of the racemic sulfide substrate should be allowed to react with the reagent containing titanium alkoxide. Limiting reaction to between about 50% to about 70% may be accomplished in at least two ways. Firstly, the hydroperoxide may be employed in quantities which provide a hydroperoxide/sulfide substrate ratio of from about 0.5/1.0 to about 0.75/1.0. Alternatively, the hydroperoxide may be used in amounts greater than about 0.75 equivalents relative to the sulfide substrate provided the progress of the reaction is monitored by standard analytical techniques such as thin layer chromatography (TLC) or high performance liquid chromatography (HPLC). Once these techniques indicate that between about 50 to about 70 percent of the sulfide starting material has been converted the reaction is quenched to prevent further conversion.

Once the reaction has been quenched the unreacted portion of the sulfide substrate may be recovered from the quenched reaction mixture using techniques well known to those skilled in the art. This unreacted portion will consist of the desired enantiomer in substantially pure enantiomeric form.

10 Example 10

5-[[3,5-Bis(1,1-dimethylethyl)-4-hydroxyphenyl]methylene]-3-(methyamino)-4-thiazolidinone

A. Preparation of benzaldehydemethylhydrazone

15

Benzaldehyde (50.8 ml, 500 mmol) and 26.5 ml (500 mmol) of methylhydrazine were dissolved in 1 liter of methanol. The mixture was stirred together at room temperature for 75 minutes and then stripped of solvent to give 67.8 g of the subtitled intermediate.

20 B. Preparation of benzaldehyde N-methyl, N-2-propenylhydrazone

25

The above compound (67.8 g), 60.5 g of allyl bromide and 50.5 g of triethylamine were dissolved together in 1 liter of acetonitrile. The mixture was heated at reflux temperature for 16 hours and then cooled. An additional 45 g of allyl bromide and 38 g of triethylamine were added and the mixture was again heated at reflux for an additional 7 hours, cooled and then stripped of solvent to yield 268 g of a residue. To this residue was added 500 ml of THF and the resultant mixture was shaken, filtered and washed with an additional 125 ml of THF. The filtrate was stripped of solvent to yield 67 g of the subtitled intermediate.

C. Preparation of N-methyl, N-2-propenyl-hydrazine

30

The above compound (59.9 g), 44 g of hydrazine and 137 ml of ethanol were heated at reflux temperature for 21.5 hours and allowed to cool. The reflux condenser was replaced with a distillation head and the mixture was distilled at one atmosphere pressure. The first three distillates were collected, combined and 100 ml of 1N HCl were added. An additional 100 ml of concentrated HCl were added, with ice, and the resultant mixture separated and washed with a small amount of ethyl acetate. The resultant layers were separated and the water distilled off until solids clogged the stir bar. The solids were filtered off and the filtrate was stripped and added to 125 ml of chilled 50% NaOH. The resulting solid was filtered off and discarded. The filtrate contained two layers which were separated. The top layer contained the subtitled intermediate and the bottom, aqueous layer, was extracted with diethyl ether which, upon stripping, gave additional product.

40

D. Preparation of N-Methyl, N-3-propenyl-5-carboxymethyl-dithiocarbamate

45

To 12.67 g of the above compound in 23 ml of ethanol chilled to 0°C was added a solution of 11.18 g of carbon disulfide in 26 ml of diethyl ether. The resultant mixture was removed from the ice bath and allowed to stand at room temperature for about 15.5 hours, after which the solvent was stripped to yield approximately 36.5 g of a residue. To this residue was added 13.9 g of chloroacetic acid dissolved in 29.5 ml of 5N NaOH (chilled in an ice bath). The resultant solution was allowed to stand for 3 hours at room temperature. The pH of the solution was lowered to about 3 by adding 8 ml of concentrated hydrochloric acid. Diethyl ether (50 ml) was then added, resulting in a three phase separation. The aqueous phases were pooled and extracted with 50 ml of chloroform, then stripped of solvent to yield approximately 40.4 g of the subtitled intermediate.

50

E. Preparation of 5-[[3,5-bis(1,1-dimethylethyl)-4-hydroxyphenyl]methylene]-2-thioxo-3-(methyl-2-propenylamino)-4-thiazolidinone

55

3,5-Di-tert-butyl-4-hydroxybenzaldehyde (29.3 g), 38.8 g of the above compound and 40.34 g of sodium acetate were mixed in 810 ml of acetic acid and the resultant solution heated at reflux temperature for 24 hours. The solution was allowed to cool and stirred for an additional 60 hours at room temperature. The solution was then poured into 2 liters of ice water, separated and washed with an additional volume of water to yield about 44 g of the subtitled intermediate.

5-[(3,5-Di-2-propenyl-4-hydroxyphenyl)methylene]-4-thiazolidinone and 5-[(3,5-Di-2-propenyl-4-hydroxyphenyl)methyl]-4-thiazolidinone

A. Preparation of 3,5-di-(2-propenyl)-4-hydroxybenzaldehyde

Under a nitrogen atmosphere and using a mechanical stirrer, 250 g of parahydroxybenzaldehyde, 247.6 g of allyl bromide, 311.7 g of potassium bicarbonate and 650 ml of acetone were heated to reflux temperature for about 18 hours. The mixture was allowed to cool, after which about 1 liter of water was added followed by extraction with two 800 ml portions of diethyl ether. Subsequent distillation of the organic phase rendered about 299 g of 4-(2-propenyl)oxybenzaldehyde which was then heated with about 300 ml of diethylaniline for 5.5 hours at 195-205°C. The mixture was cooled and 750 ml of ethyl acetate were added. The mixture was washed with three 500 ml portions of 1N HCl which, followed by subsequent workup, yielded about 138 g of 3-(2-propenyl)-4-hydroxybenzaldehyde. The mono-substituted aldehyde (159 g) was again heated to reflux with 152 g of potassium carbonate and 465 ml of acetone for 3 hours and then allowed to cool. The mixture was poured into 900 ml of ice water and subsequently extracted with two 430 ml portions of diethyl ether to yield about 170 g of 3-(2-propenyl)-4-(2-propenyloxy)-benzaldehyde. The di-substituted aldehyde was then heated, in about 500 ml of diethylaniline, under a nitrogen atmosphere to 195-205°C for about 6.5 hours. The mixture was cooled and dissolved in about 800 ml of ethyl acetate, washed with three 1 liter portions of 1N HCl and, following workup, rendered about 121.9 g of the subtitled intermediate.

the gum was dissolved in 560 ml of chloroform and the resulting solution washed, successively, with 75 ml of a saturated sodium carbonate solution, 75 ml of water and 75 ml of a saturated brine solution. The above chloroform solutions were combined and then triturated with 100 ml of methylene chloride. The titled products were obtained using silica gel chromatography. Elution with a 25-60% ethyl acetate in hexane gradient provided various fractions which were treated as follows.

Fractions 13-15 were concentrated and then washed with ethyl acetate to provide 2.91 g of 5-[(3,5-di-2-propenyl-4-hydroxyphenyl)methyl]-4-thiazolidinone. Fractions 16-18 were concentrated to a residue which was triturated with 30 ml of methylene chloride. Fractions 19-23 were concentrated to a residue which was triturated with 35 ml of methylene chloride. Following trituration, the remaining insolubles were isolated by filtration and triturated with 40 ml of ethyl acetate to provide 3.85 g of 5-[(3,5-di-2-propenyl-4-hydroxyphenyl)methylene]-4-thiazolidinone.

The ethyl acetate wash from fractions 13-15, the methylene chloride solution containing fractions 16-18 and the methylene chloride and ethyl acetate solutions obtained from fractions 19-23 were combined and loaded onto a silica gel chromatography column. 5-[[3-(1,1-dimethylethyl)-4-hydroxyphenyl]methyl]-4-thiazolidinone

A. Preparation of 3-(1,1-dimethylethyl)-4-hydroxybenzaldehyde

Into 184.4 ml (1.494 mol) of N-methylformanilide were added dropwise, with cooling, 130.9 ml (1.404 mol) of phosphoryl chloride over a period of 20 minutes. The mixture was allowed to warm to room temperature and stirred for one hour. Ortho-*tert*-butyl-phenol (138.2 ml; 0.9 mol) was then added dropwise to the reaction solution over a period of 25 minutes. After phenol addition was complete, the resulting reaction mixture was stirred for an additional 30 minutes at

room temperature and then heated to approximately 60°C and stirred for five hours at that temperature. The reaction mixture was poured into a volume of crushed ice and extracted with chloroform. The aqueous layer was separated and washed again with chloroform. The chloroform layers were combined and extracted with 2000 ml of a 5% potassium hydroxide solution. The aqueous potassium hydroxide extract was then added to 1000 ml of chloroform. The pH of the resulting two-phase mixture was adjusted to approximately pH 2.0 with concentrated hydrochloric acid. The mixture's layers were separated and the aqueous layer was again extracted with chloroform. The organic layer from the two-phase mixture and the chloroform extract were combined, washed with water and then dried over sodium sulfate. The volatile components of the solution were removed under reduced pressure to provide a residue. This residue was dissolved in 100 ml of hot toluene and the resulting solution was diluted with 100 ml of hexanes. The solution was slowly cooled to room temperature while a precipitate formed. This precipitate was recovered by filtration, washed with hexanes and then dried under vacuum to provide 20.0 g of the desired subtitled intermediate.

#### B. Preparation of 5-[[3-(1,1-dimethylethyl)-4-hydroxyphenyl]methylene]-3-amino-2-thioxo-4-thiazolidinone

The benzaldehyde intermediate from Example 29A (20.0 g; 112.2 mmol), N-aminorhodanine (18.29 g; 123.4 mmol) and sodium acetate (36.8 g; 448.8 mmol) were suspended in 560 ml of acetic acid. The suspension was heated to reflux, stirred at that temperature for 7 hours (at which time a precipitate had formed) and then cooled to room temperature with stirring. The precipitate was recovered by filtration and then washed successively with a 1:1 ethyl acetate/diethyl ether solution then a diethyl ether wash. The recovered precipitate was dried under vacuum at 60°C for 2 hours to provide 14.5 g of the desired subtitled intermediate. m.p. >225°C.

#### C. Preparation of 5-[[3-(1,1-dimethylethyl)-4-hydroxyphenyl]methylene]-4-thiazolidinone

The intermediate from Example 29B (14.3 g; 46.4 mmol) was suspended in 230 ml of hot (60°C) toluene. To this suspension were added tri-n-butyl tin hydride (62.4 ml; 232 mmol) and AIBN (1.14 g; 6.96 mmol). The resulting suspension was heated to reflux while the suspended solids slowly dissolved. Additional AIBN was added at 30 and 55 minutes (two 1.14 g portions) after heating was started. Eighty minutes after heating was started the hot reaction solution was transferred to a separatory funnel and 1N hydrochloric acid was added. The resulting two-phase mixture was diluted with ethyl acetate and the layers were separated. The aqueous layer was washed with ethyl acetate, which wash was then combined with the organic layer from the two-phase mixture. The combined solution was washed with a saturated sodium chloride solution and then dried over sodium sulfate. The volatile components of the solution were removed under reduced pressure to provide 87.7 g of a yellow solid. This solid was suspended in 1000 ml of hexanes and the resulting suspension was stirred for 15 minutes. After fifteen minutes the suspension was filtered and the recovered solid was dissolved in 500 ml of diethyl ether. The diethyl ether solution was chromatographed on a silica gel column using an 8000 ml gradient of 5-20% isopropyl alcohol in hexanes, then a 2000 ml gradient of 20-30% isopropyl alcohol in hexanes and then a 2000 ml gradient of 30-35% isopropyl alcohol in hexanes. Those fractions identified as containing product were evaporated and chased with methylene chloride. The resulting residue was dissolved in ethyl acetate, reduced to dryness under reduced pressure and then chased with ethanol to provide 4.31 g of the desired subtitled intermediate. m.p. 110°C (decomposition).

#### D. Preparation of 5-[[3-(1,1-dimethylethyl)-4-hydroxyphenyl]methyl]-4-thiazolidinone.

A portion of the intermediate from Example 29C (395.1 mg; 1.5 mmol) was dissolved in 9 ml of methanol. Magnesium (72.9 mg; 3.0 mmol) was then added to the solution and the resulting reaction mixture was stirred at room temperature for 3 hours. After 3 hours, most of the magnesium which had been added originally appeared to be gone so an additional 182.3 mg (7.5 mmol) of magnesium were added. Stirring of the reaction solution at room temperature continued overnight. By the next morning a yellow precipitate had formed. This precipitate was dissolved by adding the methanolic reaction solution to an ethyl acetate/1N hydrochloric acid mixture. The organic layer from the resulting two-phase mixture was isolated and then dried over sodium sulfate. The volatile components of the organic layer were removed and the resulting residue was chased with methylene chloride. The residue was then dissolved in 25 ml of

methylene chloride and the resulting solution was chromatographed on a silica gel chromatography column using a 5-20% isopropyl alcohol in hexanes gradient. Those fractions identified as containing essentially pure product were evaporated to provide 0.29 g of title compound. m.p. 65-70°C.

The present invention provides a method of treating inflammatory bowel disease in mammals. Such activity was demonstrated in the following test system.

Sprague-Dawley rats from Charles River Laboratories, Portage, MI (either sex, weight approximately 250 g) were dosed orally twice a day with test compound (10 mg/kg) or vehicle (control) for three days. On the third day, the rats were given an intracolonic enema of 2% acetic acid via a cannula, the tip of which was placed 8 cm above the anal verge. This concentration of acetic acid produced a severe inflammatory response in the colon characterized by rectal bleeding, diarrhea, epithelial erosions and destructions of crypts and gland cells. Twenty-four hours later the test and control animals were killed and the distal ten centimeters of the colon were removed and opened longitudinally. The tissue lesions contained within the removed, opened, section of colon were scored by three independent, blinded observers on a scale of 0 to 4 (zero = normal, four = worst inflammation). In each test group 5-7 rats were used. The results of such testing are reported in Table I, below.

Sprague-Dawley rats from Charles River Laboratories, Portage, MI (male, weight approximately 300 g) were fasted for 24 hours. After 24 hours, the test animals were dosed orally with 3 ml/kg of rat weight of vehicle (control) or test compound dissolved in vehicle. Thirty minutes later each animal was given a solution consisting of 100% ethanol. Sixty minutes after ethanol administration, all animals were killed and their stomachs were removed and washed. The tissue lesions contained within the removed, opened, stomach were scored by three independent, blinded observers on a scale of 0 to 5 (zero = normal, 5 = severe damage). In each test group, six rats were employed. Test results from animals given test compound dissolved in vehicle were compared with test results from animals given vehicle alone in order to determine the percentage of lesion inhibition attributable to the test compound. The results of such testing are reported in Table II below.

The data in Tables I and II establish that the compounds used in the method of the present invention can treat inflammatory bowel disease. The term "inflammatory bowel disease", as used for purposes of the present invention, means any disorder of the digestive system which is characterized by inflammation. Examples of such disorders include Crohn's disease, mucous colitis, ulcerative colitis, pseudomembranous enterocolitis, non-specific colonic ulcers, collagenous colitis, cathartic colon, ulcerative proctitis, radiation enteritis and colitis, idiopathic diffuse ulcerative nongranulomatous enteritis, nonsteroidal antiinflammatory drug induced inflammations, celiac sprue and the like.

The method of the present invention comprises administering to a mammal suffering from inflammatory bowel disease an effective amount of one or more of the compounds of Formula I. Administration may be done either therapeutically or prophylactically and is accomplished by means of pharmaceutical compositions which are prepared by techniques well known in the pharmaceutical sciences.

The compounds of Formula I are effective over a wide dosage range in treating inflammatory bowel disease. Thus, as used herein, the term "effective amount" refers to a dosage range of from about 0.001 to about 200 mg/kg of body

weight per day. In the treatment of adult humans, the range of about 0.1 to about 50 mg/kg, in single or divided doses, is preferred. However, it will be understood that the amount of compound actually administered will be determined by a physician in light of the relevant circumstances, including the condition to be treated, the choice of compound to be administered, the chosen route of administration, the age, weight, and response of the individual patient, and the severity of the patient's symptoms. Therefore, the above dosage ranges are not intended to limit the scope of the invention in any way.

While the compounds of Formula I are preferably administered orally or intrarectally, the compounds may also be administered by a variety of other routes such as the transdermal, subcutaneous, intranasal, intramuscular and intravenous routes.

The present invention provides new compounds of Formula II which are also useful in treating inflammatory bowel disease. Accordingly, the present invention is also directed to pharmaceutical compositions which include at least one compound of Formula II in association with one or more pharmaceutically acceptable diluents, excipients or carriers therefor.

In making the pharmaceutical compositions of the present invention, one or more compounds of Formula II will usually be mixed with a carrier, or diluted by a carrier, or enclosed within a carrier which may be in the form of a capsule, sachet, paper or other container. When the carrier serves as a diluent, it may be a solid, semi-solid or liquid material which acts as a vehicle, excipient or medium for the active ingredient. Thus, the compositions can be in the form of tablets, pills, powders, lozenges, sachets, cachets, elixirs, suspensions, emulsions, solutions, syrups, aerosols (as a solid or in a liquid medium), ointments containing for example up to 10% by weight of active compound, soft and hard gelatin capsules, suppositories, sterile injectable solutions and sterile packaged powders.

Some examples of suitable carriers, excipients, and diluents include lactose, dextrose, sucrose, sorbitol, mannitol, starches, gum acacia, calcium phosphate, alginates, tragacanth, gelatin, calcium silicate, microcrystalline cellulose, polyvinylpyrrolidone, cellulose, water, syrup, methyl cellulose, methyl - and propylhydroxybenzoates, talc, magnesium stearate and mineral oil. The formulations can additionally include lubricating agents, wetting agents, emulsifying and suspending agents, preserving agents, sweetening agents or flavoring agents. The compositions of the invention may be formulated so as to provide rapid, sustained or delayed release of the active ingredient after administration to the patient by employing procedures well known in the art.

The compositions are formulated, preferably in a unit dosage form, such that each dosage contains from about 5 to about 500 mg, more usually about 25 to about 300 mg, of the active ingredient. The term "unit dosage form" refers to physically discrete units suitable as unitary dosages for human subjects and other mammals, each unit containing a predetermined quantity of active material calculated to produce the desired therapeutic effect, in association with one or more suitable pharmaceutical diluents, excipients or carriers.

The following formulation examples may employ as active ingredients any of the compounds of Formula II. The examples are illustrative only and are not intended to limit the scope of the invention in any way.
